# Clifford Wavelets and Clifford-valued MRAs 

A. Askari Hemmat ${ }^{a}$ and Z. Rahbani ${ }^{b, *}$<br>${ }^{a}$ Department of Mathematics, Shahid Bahonar University of Kerman, Kerman, Iran<br>${ }^{b}$ Department of Mathematics, Vali-e-Asr University, Rafsanjan, Iran<br>E-mail: askari@mail.uk.ac.ir<br>E-mail: zrahbani@mail.vru.ac.ir

#### Abstract

In this paper using the Clifford algebra over $\mathbb{R}^{4}$ and its matrix representation, we construct Clifford scaling functions and Clifford wavelets. Then we compute related mask functions and filters, which arise in many applications such as quantum mechanics.

Keywords: Clifford Wavelets, Clifford algebra, Multiresolution Analysis, Wavelets.

2000 Mathematics subject classification: 42C15, 46E15, 50C20, 42B99, 42C05.

## 1. Introduction

A complex-valued representation of a real 1-dimensional signal is an important tool in analysis of signal processing. The reason is that in its polar representation, the modulus of the complex signal is identified as a local quantitative measure of a signal, called local amplitude, and the argument of the complex signal is identified as a local measure for the qualitative information of a signal, called local phase. First step for generalizing such representation system was quaternion-valued representation, on which a signal can be expressed by four parameters as its local quantitative measures.

[^0]On the other hand wavelets are a very useful and wide applied tools for practical applications in signal and image processing, multi-satellite measurements of electromagnetic wave fields, analysis of climate-related time-series and analysis space weather effects and so on. One usual way to construct wavelets pass through multiresolution analysis (MRA), which is a procedure for constructing wavelets from a scaling function. Now if the scaling function is a matrix of functions, we deal with matrix-valued MRAs. In this paper we show that any real or complex Clifford algebra can be identified with a suitable matrix algebra, then via this representation, Clifford-valued scaling functions, Clifford-valued MRAs and Clifford wavelets are given.
Notations. For an algebra $\mathbb{K}$, we denote its product with ".". $\mathbb{R}, \mathbb{C}$ and $\mathbb{H}$ are algebra of real numbers, complex numbers and quaternions, respectively. $\mathbb{K}[n]$ is the algebra of $n \times n$ matrices over field $\mathbb{K}$. $\otimes_{\mathbb{K}}$ denotes tensor product over field $\mathbb{K}$.

This paper is organized as follow: in second section we introduce the ndimensional Clifford algebra (on brief) and some useful theorems on it, then we discuss the $C l\left(\mathbb{R}^{4}\right)$ and $\mathbb{C l}\left(\mathbb{R}^{4}\right)$ (real and complex forms of Clifford algebra on $\mathbb{R}^{4}$, resp.) and their matrix representations. Section 3 consists of multiresolition analysis (MRA) and Clifford wavelet structures. In section 4, we compute Clifford wavelets matrices on $\mathbb{R}^{4}$.

## 2. Clifford Algebra

In this section we mention some definitions and basic facts about Clifford algebras.

Definition 2.1. let $V$ be a finite dimensional vector space on the field $\mathbb{F}$. A quadratic form (q-form) on $V$ is a function $h: V \times V \longrightarrow \mathbb{F}$, such that
$h\left(\alpha x_{1}+x_{2}, y\right)=\alpha h\left(x_{1}, y\right)+h\left(x_{2}, y\right)$
$h\left(x, \alpha y_{1}+y_{2}\right)=\alpha h\left(x, y_{1}\right)+h\left(x, y_{2}\right)$.
Furthermore if $h(x, y)=h(y, x)$ then $h$ is called symmetric. For any q-form $h$, there exists a matrix representation $A=\left(A_{i j}\right)$ such that $A_{i j}=h\left(e_{i}, e_{j}\right)$ where $\left\{e_{1}, e_{2}, \cdots, e_{n}\right\}$ is a basis for $V$. The q-form $h$ is called nondegenerate, if $\operatorname{det}\left(h\left(e_{i}, e_{j}\right)\right) \neq 0$.
Let $V$ be an $n$-dimensional vector space on the field $F$, and $h$ be a nondegenerate symmetric q-form on $V$, then there exists an ordered basis $B=$ $\left\{e_{1}, e_{2}, \cdots, e_{n}\right\}$ for $V$ such that $A=\left(A_{i j}\right)$ is diagonal. In particular for $\mathbb{F}=\mathbb{R}$

$$
h\left(e_{i}, e_{j}\right)=\left\{\begin{array}{cl} 
\pm 1 & \text { if } i=j \\
0 & \text { otherwise }
\end{array}\right.
$$

If the matrix $A$ have $p$-times 1 and $q$-times -1 on its diameter such that $p+$ $q=n$, then $h$ will be shown with $h(p, q)$. For $h$, a nondegenerate q-form on
real vector space $V$, the pair $(V, h)$ is called a quadratic space(q-space). For describing the Clifford algebra on vector space $V$, consider the commutative tensor algebra $T(V)=\bigoplus_{r=0}^{\infty} \otimes^{r} V$ on real q-space $(V, h)$ with unit 1 . Let $I_{h}(V)=\langle V \otimes V+h(V, V)\rangle$ then $I_{h}$ is a two-sided ideal in $T(V)$. The quotient space $\frac{T(V)}{I_{h}(V)}$ is called the Clifford algebra on $V$ and is denoted by $C l(V, h)$. The induced product, from tensor product on $\mathrm{T}(\mathrm{V})$, is called Clifford product and will be shown with ".", $(C l(V, h), " . ")$ is again a commutative algebra with unit. If $h$ is $h(p, q)$ then $C l(V, h)$ will be shown by $C l(p, q)$.
By considering the canonical projection map $\pi_{h}: T(V) \longrightarrow C l(V, h)$, one can find that the map $\theta_{V}: V \longrightarrow C l(V, h)$ is one-to-one. This fact says that $C l(V, h)$ is generated by vector space $V \subset C l(V, h)$ and identity 1 , and its product satisfies the following relations:

1) $v \cdot v=-h(v, v) 1 \quad$ for any $v \in C l(V, h)$
2) $v \cdot w+w \cdot v=-2 h(v, w)$.

In view of previous equations we can obtain the universal map for Clifford algebras as follow:

Proposition 2.1. Let $\mathcal{A}$ be a commutative $\mathbb{K}$-Algebra with unit 1 , and $f$ : $V \longrightarrow \mathcal{A}$ be a linear map such that: $f(v) \cdot f(v)=-h(v, v) 1$ for any $v \in V$, then $f$ can be uniquely extended to the algebraic homomorphism $\widetilde{f}: C l(V, h) \longrightarrow \mathcal{A}$. Furthermore, $C l(V, h)$ is the unique associated $\mathbb{K}$-Algebra with this property.

In other word if $(V, h)$ is a q-space, then there exists a Clifford algebra associated to it and is unique up to an isomorphism. This is easy to show that if $\left\{e_{1}, e_{2}, \cdots, e_{n}\right\}$ is an orthonormal basis for real vector space $V$, then the set $\left\{1, e_{i}, e_{i} e_{j}, e_{i} e_{j} e_{k}, \cdots, e_{1} e_{2} e_{3} \cdots e_{n}: i+1=j, j+1=k\right\}$ is a basis for $C l(V, h)$. Note that $C l(V, h)=\frac{T(V)}{I_{h}}=\frac{R \oplus V \otimes V \oplus V \otimes V \otimes V \oplus \cdots}{\langle V \otimes V+h(V) 1\rangle}$, and
$T(V)=a_{0}+\sum_{i=1}^{n} a_{i} e_{i}+\sum a_{i j} e_{i} \otimes e_{j}+\sum a_{i j k} e_{i} \otimes e_{j} \otimes e_{k}+\cdots+a_{i_{1} \ldots i_{n}} e_{1} \otimes e_{2} \otimes \ldots \otimes e_{n}$.
Also $V \otimes V+h(V) 1=0 \quad$ implies that $\quad V \otimes V=-h(V) 1$.
Example 2.2. Let $V=R^{2}$, and $h$ be the quadratic form obtained by the matrix

$$
\begin{aligned}
& h=\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right), \text { i.e } V=\mathbb{R}^{2}=\left\langle e_{1}, e_{2}\right\rangle . \operatorname{Dim} V=2, \text { so } \operatorname{dim} C l(V)=4 \text { and } \\
& \begin{aligned}
C l(V) & =C l\left(\mathbb{R}^{2}\right)=\left\langle 1, e_{1}, e_{2}, e_{1} e_{2}\right\rangle \\
& =\left\{a_{0}+a_{1} e_{1}+a_{2} e_{2}+a_{12} e_{1} e_{2}: e_{1}^{2}=e_{2}^{2}=-1, e_{1} \cdot e_{2}=-e_{2} \cdot e_{1}\right\}
\end{aligned}
\end{aligned}
$$

where $\left(e_{1} \cdot e_{2}\right)^{2}=e_{1} e_{2} e_{1} e_{2}=-e_{1} e_{1} e_{2} e_{2}=(-1)(-1)(-1)=-1$.
So if we define $\psi: C l\left(\mathbb{R}^{2}\right) \longrightarrow \mathbb{H}$ by

$$
\psi(1)=1, \psi\left(e_{1}\right)=i, \psi\left(e_{2}\right)=j, \psi\left(e_{1} e_{2}\right)=\psi\left(e_{3}\right)=k
$$

then, since $\psi$ is an algebraic homomorphism, $C l\left(\mathbb{R}^{2}\right) \cong \mathbb{H}$.

There are useful algebraic isomorphisms for $C l(p, q)$ such as

$$
\begin{gather*}
C l(n, 0) \otimes C l(0,2) \cong C l(0, n+2)  \tag{2.1}\\
C l(0, n) \otimes C l(2,0) \cong C l(n+2,0) \\
C l(p, q) \otimes C l(1,1) \cong C l(p+1, q+1),
\end{gather*}
$$

where $n, p, q \geq 0$ such that $n=p+q$.
Now we introduce a useful tool. Complexification is one of the important tools in linear algebra which make it more flexible. Let $(V, h)$ be a real q-space. The complexification of $V$ is the vector space $W=V \otimes_{\mathbb{C}} \mathbb{C}$ such that for $w \in W: w=v \otimes \lambda=v \otimes(a+i b)=v \otimes a+v \otimes i b=1 \otimes a v+i(1 \otimes b v)$. This means that any element of $W$ can be written as $x+i y$ where $x, y \in V$. Now let $g$ be a nondegenerate q -form on $V$. Then $g_{W}: W \times W \longrightarrow \mathbb{C}$ is a nondegenerate q-form on $W=V \otimes \mathbb{C}$ defined by $g_{W}(x \otimes \lambda, y \otimes \gamma)=\lambda \gamma g(x, y)$. From this point of view the complexification of $C l(V)$ is $C l(V) \otimes \mathbb{C}$ and if $W=V \otimes_{\mathbb{C}} \mathbb{C}$ then $C l(W)=C l(V) \otimes_{\mathbb{R}} \mathbb{C}$.

Lemma 2.3. Let $V$ be a real $n$-dimensional vector space, then

$$
\mathbb{C} l\left(V \oplus \mathbb{R}^{2}\right) \otimes \mathbb{C} \cong\left(C l(V) \otimes_{\mathbb{R}} \mathbb{C}\right) \otimes_{\mathbb{C}}\left(C l\left(\mathbb{R}^{2}\right) \otimes \mathbb{C}\right) .
$$

Proof. Let $\left\{\nu_{1}, \cdots, \nu_{n}\right\}$ be an orthonormal basis for $V$ and $\left\{e_{1}, e_{2}\right\}$ be the standard basis for $\mathbb{R}^{2}$. Consider the real map $\theta: V \oplus \mathbb{R}^{2} \longrightarrow\left(C l(V) \otimes_{\mathbb{R}} \mathbb{C}\right) \otimes_{\mathbb{C}}$ $\left(C l\left(\mathbb{R}^{2}\right) \otimes \mathbb{C}\right)$ defined by

$$
\left(\nu_{j}, 0\right) \longmapsto i \nu_{j} \otimes e_{1} e_{2}, \quad 1 \leq j \leq n, \quad\left(0, e_{r}\right) \longmapsto 1 \otimes e_{r} r=1,2 .
$$

so $\theta$ extends to algebra homomorphism $\mathbb{C l}\left(V \oplus \mathbb{R}^{2}\right) \otimes \mathbb{C} \cong\left(C l(V) \otimes_{\mathbb{R}} \mathbb{C}\right) \otimes_{\mathbb{C}}$ $\left(C l\left(\mathbb{R}^{2}\right) \otimes \mathbb{C}\right)$. On the other hand domain and range of $\theta$ have the same dimension and it is onto, so $\theta$ is isometry.
the following lemma is the key tool for describing the complex Clifford algebras.

Lemma 2.4. Let $V$ be a real vector space such that $\operatorname{dim} V=2 n$, then $C l(V) \otimes_{\mathbb{R}} \mathbb{C}$ is isomorphic to the matrix algebra $\mathbb{C}\left[2^{n}\right]$. If $\operatorname{dim} V=2 n+1$ then $C l(V) \otimes_{\mathbb{R}} \mathbb{C}$ is isomorphic to $\mathbb{C}\left[2^{n}\right] \oplus \mathbb{C}\left[2^{n}\right]$.

Proof. We refer interested reader to [2], for an extended proof.
2.1. Construction of Clifford Algebra on $\mathbb{R}^{4}$. Now we are going to show that for $V=\mathbb{R}^{4}, C l(V)$ is $\mathbb{H}[2] \cong \mathbb{C}[4]$. We know that, via the algebraic isomorphism

$$
a+b i+c j+d k \longmapsto\left(\begin{array}{rr}
a+i d & b+i c \\
-b+i c & a-i d
\end{array}\right),
$$

$\mathbb{H}$ is isomorphic to $\mathbb{C}[2]$. Now if $V=\mathbb{R}^{4}=\left\langle e_{0}, e_{1}, e_{2}, e_{3}\right\rangle$ with Riemannian form $h=\left(\begin{array}{llll}1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1\end{array}\right)$ on it, then
$C l\left(\mathbb{R}^{4}\right)=\left\{a_{0}+\sum_{i=1}^{4} a_{i} e_{i}+\sum_{i<j} a_{i j} e_{i} e_{j}+\sum_{i<j<k} a_{i j k} e_{i} e_{j} e_{k}+a_{1234} e_{1} e_{2} e_{3} e_{4}: e_{i} e_{j}=-e_{j} e_{i}, e_{i}^{2}=-1, a_{i} \in \mathbb{R}\right\}$
this means that $C l\left(\mathbb{R}^{4}\right)$ is spanned by $2^{4}=16$ vectors:

$$
\begin{gathered}
1, E_{1}, E_{2}, E_{3}, E_{4}, E_{1} E_{2}, E_{1} E_{3}, E_{1} E_{4}, E_{2} E_{3}, E_{2} E_{4}, E_{3} E_{4} \\
E_{1} E_{2} E_{3}, E_{1} E_{2} E_{4}, E_{1} E_{3} E_{4}, E_{2} E_{3} E_{4}, E_{1} E_{2} E_{3} E_{4}
\end{gathered}
$$

as a basis. On the other hand

$$
C l(0,2)=C l\left(\mathbb{R}^{2},\left(\begin{array}{rr}
-1 & 0 \\
0 & -1
\end{array}\right)\right)=\left\langle e_{0}, e_{1}, e_{2}, e_{3}=e_{1} e_{2}\right\rangle
$$

where $e_{0}=\left(\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right), e_{1}=\left(\begin{array}{ll}0 & 1 \\ 1 & 0\end{array}\right), e_{2}=\left(\begin{array}{rr}1 & 0 \\ 0 & -1\end{array}\right), e_{3}=\left(\begin{array}{rr}0 & -1 \\ 1 & 0\end{array}\right)$ such that $e_{0}^{2}=e_{1}^{2}=e_{2}^{2}=1,\left(e_{1} e_{2}\right)^{2}=-1$ and

$$
C l(2,0)=C l\left(\mathbb{R}^{2},\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right)\right) \cong \mathbb{H}=\left\langle e_{0}^{\prime}, e_{1}^{\prime}, e_{2}^{\prime}, e_{3}^{\prime}=e_{1}^{\prime} e_{2}^{\prime}\right\rangle
$$

where $e_{0}{ }^{\prime}=\left(\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right), e_{1}{ }^{\prime}=\left(\begin{array}{rr}0 & 1 \\ -1 & 0\end{array}\right), e_{2}{ }^{\prime}=\left(\begin{array}{cc}0 & i \\ i & 0\end{array}\right), e_{3}{ }^{\prime}=\left(\begin{array}{rr}i & 0 \\ 0 & -i\end{array}\right)$.
Now if in (2.1) we set $n=2$ then

$$
C l(0,2) \otimes C l(2,0) \cong C l(4,0)
$$

Through the relation $A \otimes B=\left(A_{i j} B\right)$ between matrices we can find the matrix representation for $C l(4,0)$ 's bases:
$E_{0}=e_{0} \otimes e_{0}^{\prime}=I, E_{1}=e_{0} \otimes e_{3}^{\prime}, E_{2}=e_{2} \otimes e_{1}^{\prime}, E_{3}=e_{1} \otimes e_{1}^{\prime}, E_{4}=$ $e_{0} \otimes e_{2}^{\prime}, \quad E_{1} E_{2}=e_{2} \otimes e_{2}^{\prime}, \quad E_{1} E_{3}=e_{1} \otimes e_{2}^{\prime}, \quad E_{1} E_{4}=-\left(e_{0} \otimes e_{1}^{\prime}\right), \quad E_{2} E_{3}=$ $e_{3} \otimes e_{0}^{\prime}, \quad E_{2} E_{4}=e_{1} \otimes e_{3}^{\prime}, \quad E_{3} E_{4}=e_{2} \otimes e_{3}^{\prime}, \quad E_{1} E_{2} E_{3}=e_{3} \otimes e_{3}^{\prime}, \quad E_{1} E_{2} E_{4}=$ $-\left(e_{2} \otimes e_{0}^{\prime}\right), \quad E_{2} E_{3} E_{4}=e_{3} \otimes e_{2}^{\prime}, \quad E_{1} E_{3} E_{4}=-\left(e_{1} \otimes e_{0}^{\prime}\right), E_{1} E_{2} E_{3} E_{4}=-\left(e_{3} \otimes\right.$ $\left.e_{1}^{\prime}\right)$.
This means that for any $\rho \in C l\left(\mathbb{R}^{4}\right)$ we have

$$
\begin{gathered}
\rho=a_{0}+a_{1} E_{1}+a_{2} E_{2}+a_{3} E_{3}+a_{4} E_{4}+a_{12} E_{1} E_{2}+a_{13} E_{1} E_{3}+a_{14} E_{1} E_{4}+a_{24} E_{2} E_{4} \\
+ \\
+a_{34} E_{3} E_{4}+a_{23} E_{2} E_{3}+a_{123} E_{1} E_{2} E_{3}+a_{124} E_{1} E_{2} E_{4} \\
+a_{234} E_{2} E_{3} E_{4}+a_{134} E_{1} E_{3} E_{4}+a_{1234} E_{1} E_{2} E_{3} E_{4}
\end{gathered}
$$

By the above matrix representation for $E_{i}$ 's, associated matrix to $\rho$ is:

$$
\left(\begin{array}{llll}
a_{0}+a_{1} i+a_{34} i- & a_{2}+a_{4} i+a_{12} i- & -a_{24} i-a_{23}-a_{123} i- & a_{3}+a_{13} i a_{234} i+ \\
a_{124} & a_{14} & a_{134} & a_{1234} \\
-a_{2}+a_{4} i+a_{12} i+ & a_{0}-a_{1} i-a_{34} i- & -a_{3}+a_{13} i-a_{234} i- & -a_{23}+a_{24} i+a_{123} i- \\
a_{14} & a_{124} & a_{1234} & a_{134} \\
a_{23}+a_{24} i+a_{123} i- & a_{3}+a_{13} i+a_{234} i- & a_{0}+a_{1} i-a_{34} i+ & -a_{2}+a_{4} i-a_{12} i- \\
a_{134} & a_{1234} & a_{124} & a_{14} \\
-a_{3}+a_{13} i+a_{234} i+ & a_{23}-a_{24} i-a_{123} i- & a_{2}+a_{4} i-a_{12} i+ & a_{0}-a_{1} i+a_{34} i+ \\
a_{1234} & a_{134} a & a_{14} & a_{124}
\end{array}\right)
$$

Now if we set
$A_{1}=a_{0}+i a_{1}, \quad B_{1}=-a_{124}+i a_{34}, \quad A_{2}=a_{2}+i a_{4}, \quad B_{2}=a_{14}+i a_{12}, \quad A_{3}=$ $a_{23}+i a_{24}, \quad B_{3}=-a_{134}+i a_{123}, \quad A_{4}=a_{3}+i a_{13}, \quad B_{4}=a 1234+i a_{234}$, and then set $A=A_{1}+B_{1}, \quad B=A_{1}-B_{1}, \quad C=A_{2}-\overline{B_{2}}, \quad D=A_{2}+\overline{B_{2}}$, $E=A_{3}+B_{3}, \quad F=-A_{3}+B_{3}, \quad G=A_{4}+\overline{B_{4}}, \quad H=A_{4}-\overline{B_{4}}, \rho$ can be shown as

$$
\rho \cong\left(\begin{array}{cccc}
A & -C & F & -G  \tag{2.2}\\
\bar{C} & \bar{A} & \bar{G} & \bar{F} \\
E & -H & B & -D \\
\bar{H} & \bar{E} & \bar{D} & \bar{B}
\end{array}\right):=M_{Q}
$$

A simpler representation for $\rho$ is $\rho=\left(\begin{array}{ll}\alpha & \beta \\ \gamma & \lambda\end{array}\right)$, which is a $2 \times 2$-matrix in $\mathbb{H}$, with $\alpha=A-j \bar{C}, \beta=F-j \bar{G}, \gamma=E-j \bar{H}, \lambda=B-j \bar{D}$.
Till now we've found the matrix representations for $C l\left(\mathbb{R}^{4}\right)$ such that $\mathbb{H}[2] \cong$ $\mathbb{C}[4]$. By considering the complexification of $C l\left(\mathbb{R}^{4}\right)$ we will work with $\mathbb{C}[4]$, which is a more general and flexible case.
Let $M_{Q}$ be the set of all $4 \times 4$-matrices in $\mathbb{C}[4]$ which are like above then $M_{Q}$ excepting the zero matrix is a subgroup of $G L(2, \mathbb{C})$ in the sense of matrix multiplication.
In next step we generalize these concepts to an MRA.

## 3. $\mathbb{C l}\left(\mathbb{R}^{4}\right)$-valued MRA

3.1. General construction and mask functions. Let $L^{2}(\mathbb{R}, \mathbb{C}[r])=\{\mathbf{F}(t)=$ $\left.\left(F_{m, n}(t)\right): t \in \mathbb{R}, F_{m, n} \in L^{2}(\mathbb{R}), 1 \leq m, n \leq r\right\}$ be the space of matrixvalued functions defined on $\mathbb{R}$ with values in $\mathbb{C}[r]$. The norm on $L^{2}(\mathbb{R}, \mathbb{C}[r])$ is the Ferobenious norm : $\|\mathbf{F}(t)\|=\left[\sum_{m, n} \int_{\mathbb{R}}\left|F_{m, n}(t)\right|^{2} d t\right]^{\frac{1}{2}} \quad$ and for $\mathbf{F}, \mathbf{G} \in$ $L^{2}(\mathbb{R}, \mathbb{C}[r])$, the "inner product" is defined by $\langle\mathbf{F}, \mathbf{G}\rangle_{L^{2}(\mathbb{R}, \mathbb{C}(r))}:=\int_{\mathbb{R}} \mathbf{F}(t) \mathbf{G}^{\dagger}(t) d t$ where $\mathbf{G}^{\dagger}$ is the complex conjugate transpose of $\mathbf{G}$. As pointed out in [7] and [8] such operation, which is an integral of matrix product, is not really an inner product but it has the linear and commutative properties:

1. $\left\langle\mathbf{F}_{1}, a \mathbf{F}_{2}+b \mathbf{F}_{3}\right\rangle=a^{\dagger}\left\langle\mathbf{F}_{1}, \mathbf{F}_{2}\right\rangle+b^{\dagger}\left\langle\mathbf{F}_{1}, \mathbf{F}_{3}\right\rangle$
2. $\left\langle\mathbf{F}_{1}, \mathbf{F}_{2}\right\rangle=\left\langle\mathbf{F}_{2}, \mathbf{F}_{1}\right\rangle^{\dagger}$.

Here the orthogonality of $\mathbf{F}_{j}$ and $\mathbf{F}_{k}$ is identified with $\left\langle\mathbf{F}_{j}, \mathbf{F}_{k}\right\rangle=I_{r} \delta_{j k}$ where $I_{r}$ is identity matrix and $\delta_{j k}$ the Kronecker delta. Now let $\mathbf{X}(t)$ be a $\mathbb{C l}\left(\mathbb{R}^{4}\right)$ valued function. Then $\mathbf{X}(t)$ via its components has a representation like $M_{Q}$, as shown in (2.2) and matrix representation of $\mathbf{X}(t)$ is shown with $M_{Q}(\mathbf{X})$. Define $L_{M_{Q}}^{2}(\mathbb{R}, \mathbb{C}[4])=\left\{M_{Q}(\mathbf{X}): x_{i j} \in L^{2}(\mathbb{R}), 1 \leq i, j \leq 4\right\} \subseteq L^{2}(\mathbb{R}, \mathbb{C}[4])$, and

$$
L^{2}\left(\mathbb{R}, \mathbb{C} l\left(\mathbb{R}^{4}\right)\right)=\left\{\mathbf{X}(t)=x_{0}(t)+x_{1}(t) E_{1}+\ldots+x_{1234}(t) E_{1234}: x_{i} \in L^{2}(\mathbb{R})\right\}
$$

then we can identify $L^{2}\left(\mathbb{R}, \mathbb{C l}\left(\mathbb{R}^{4}\right)\right)$ with $L_{M_{Q}}^{2}(\mathbb{R}, \mathbb{C}[4])$ by $T: L^{2}\left(\mathbb{R}, \mathbb{C l}\left(\mathbb{R}^{4}\right)\right) \longrightarrow$ $L_{M_{Q}}^{2}(\mathbb{R}, \mathbb{C}[4])$ such that

$$
\mathbf{X}(t) \longmapsto\left(\begin{array}{cccc}
x_{A} & -x_{C} & x_{F} & -x_{G} \\
\bar{x}_{C} & \bar{x}_{A} & \bar{x}_{G} & \bar{x}_{F} \\
x_{E} & -x_{H} & x_{B} & -x_{D} \\
\bar{x}_{H} & \bar{x}_{E} & \bar{x}_{D} & \bar{x}_{B}
\end{array}\right)=M_{Q}(\mathbf{X})
$$

where $x_{A}=x_{0}(t)+i x_{1}(t)+i x_{34}(t)-x_{124}(t)$ and all other entries are similar to $M_{Q}$ 's entries.
Immediately we realize that $\langle\mathbf{X}, \mathbf{Y}\rangle_{L^{2}\left(\mathbb{R}, \mathbb{C} l\left(\mathbb{R}^{4}\right)\right)} \longmapsto\left\langle M_{Q}(\mathbf{X}), M_{Q}(\mathbf{Y})\right\rangle_{L_{M_{Q}}^{2}}(\mathbb{R}, \mathbb{C}[4])$, where $\langle\mathbf{X}, \mathbf{Y}\rangle_{L^{2}\left(\mathbb{R}, \mathbb{C} l\left(\mathbb{R}^{4}\right)\right)}=\int_{\mathbb{R}} \mathbf{X} \mathbf{Y}^{\dagger} d t$.
Now by considering $\mathbb{C l}\left(\mathbb{R}^{4}\right) \cong \mathbb{C}[4]$, we will investigate some results in matrixvalued MRAs.

Definition 3.1. The matrix-valued function $\Phi(t)=\left(\varphi_{m, n}(t)\right)_{r \times r} \in L^{2}(\mathbb{R}, \mathbb{C}[r])$ generates a matrix-valued multiresolution analysis for $L^{2}(\mathbb{R}, \mathbb{C}[r])$ if the subspaces $\mathbf{V}_{j}=\operatorname{span}\left\{2^{\frac{j}{2}} \Phi\left(2^{j} t-k\right): k \in \mathbb{Z}\right\}$ are nested: $\cdots \subset \mathbf{V}_{-1} \subset \mathbf{V}_{0} \subset$ $\mathbf{V}_{1} \subset \mathbf{V}_{2} \cdots$, and the following conditions hold:

1) $\overline{\bigcup_{j \in \mathbb{Z}} \mathbf{V}_{j}}=L^{2}(\mathbb{R}, \mathbb{C}[r])$,
2) $\cap \mathbf{V}_{j}=0_{r}$, in which $0_{r}$ is the $r \times r$-zero matrix.
3) $\mathbf{X}(t) \in \mathbf{V}_{0} \Longleftrightarrow \mathbf{X}\left(2^{j} t\right) \in \mathbf{V}_{j}, \quad j \in \mathbb{Z}$,
4) $\mathbf{X}(t) \in \mathbf{V}_{0} \Longleftrightarrow \mathbf{X}(t-k) \in \mathbf{V}_{0}, \quad k \in \mathbb{Z}$,
5) $\{\Phi(t-k): k \in \mathbb{Z}\}$ form an orthonormal basis for $\mathbf{V}_{0}$.

Remark 3.1. : A sequence $\left\{\Phi_{k}\right\}_{k \in \mathbb{Z}}$ in $L^{2}(\mathbb{R}, \mathbb{C}(r))$ is called an orthonormal basis if it is an orthonormal set, $\left\langle\Phi_{j}, \Phi_{k}\right\rangle=\boldsymbol{I}_{r} \delta_{j k}$, and for any $\boldsymbol{X}(t) \in$ $L^{2}(\mathbb{R}, \mathbb{C}[r])$ there exists constant matrix-sequence $\left\{\boldsymbol{A}_{k}\right\}_{k \in \mathbb{Z}}$ such that $\boldsymbol{X}(t)=$ $\sum_{k \in \mathbb{Z}} \boldsymbol{A}_{k} \Phi_{k}(t)$.

Condition (5) means that $X(t)=\sum_{k \in \mathbb{Z}} \mathbf{A}_{k} \Phi_{k}(t-k)$, which Ferobenious norm will guarantee the convergence of infinite sum, and $\mathbf{A}_{k}=\left\langle X, \Phi_{k}(t-k)\right\rangle$ by orthonormality. Also since $\Phi(t) \in \mathbf{V}_{0} \subset \mathbf{V}_{1}$, then the two-scale matrix dilation equation is

$$
\begin{equation*}
\Phi(t)=\sqrt{2} \sum_{k \in \mathbb{Z}} \mathbf{G}_{k} \Phi(t-k) \tag{3.1}
\end{equation*}
$$

which combined with orthonormality of $\Phi$ 's means

$$
\begin{equation*}
\sum_{k \in \mathbb{Z}} \mathbf{G}_{k} \mathbf{G}_{2 l+k}^{\dagger}=\mathbf{I}_{r} \delta_{l 0}, \quad l \in \mathbb{Z} . \tag{3.2}
\end{equation*}
$$

Let $\widehat{\mathbf{G}}(f)=\sum_{k \in \mathbb{Z}} \mathbf{G}_{k} e^{-2 \pi i k f}$ be the matrix mask function, then (3.2) implies that

$$
\begin{equation*}
\widehat{\mathbf{G}}(f) \widehat{\mathbf{G}}^{\dagger}(f)+\widehat{\mathbf{G}}\left(f+\frac{1}{2}\right) \widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right)=2 I_{r}, \tag{3.3}
\end{equation*}
$$

Define matrix Fourier transform for $\Phi(t)$ by $\widehat{\Phi}(f):=\int_{\mathbb{R}} \Phi(t) e^{-2 \pi i k f t} d t$. Then (3.1) gives $\widehat{\Phi}(f)=\frac{1}{\sqrt{2}} \widehat{\mathbf{G}}\left(\frac{f}{2}\right) \widehat{\phi}\left(\frac{f}{2}\right)$, where by setting $f=0$ we get $\widehat{\mathbf{G}}(0)=$ $\sum \mathbf{G}_{k}=\sqrt{2} \mathbf{I}_{r}, \widehat{\mathbf{G}}\left(\frac{1}{2}\right)=0$. Define the function matrix $\Psi(t)=\left(\psi_{m, n}(t)\right)_{r \times r} \in$ $L^{2}(\mathbb{R}, \mathbb{C}[r])$ and corresponding subspace $\mathbf{W}_{j}=\operatorname{span}\left\{2^{\frac{j}{2}} \Psi\left(2^{j} t-k\right): k \in\right.$ $\mathbb{Z}\} . \mathbf{W}_{j}$ is orthogonal complement of $\mathbf{V}_{j}$ in $\mathbf{V}_{j+1}$ i.e. $\mathbf{V}_{j+1}=\mathbf{V}_{j} \oplus \mathbf{W}_{j}$, $\mathbf{V}_{j} \perp \mathbf{W}_{j}$ and $\bigoplus_{j \in \mathbb{Z}} \mathbf{W}_{j}=L^{2}(\mathbb{R}, \mathbb{C}[r])$. Since $\Psi(t) \in \mathbf{W}_{0} \subseteq \mathbf{V}_{1}$, then $\Psi(t)=\sqrt{2} \sum_{k \in \mathbb{Z}} \mathbf{H}_{k} \Phi(2 t-k)$. Combining this formula with (3.1) gives us

$$
\begin{equation*}
\sum_{k \in \mathbb{Z}} \mathbf{G}_{k} \mathbf{H}_{2 l+k}^{\dagger}=0_{r}, \quad l \in \mathbb{Z} . \tag{3.4}
\end{equation*}
$$

Now if $\widehat{\mathbf{H}}(f)=\sum_{k \in \mathbb{Z}} \mathbf{H}_{k} e^{-2 \pi i k f}$ then

$$
\begin{equation*}
\widehat{\mathbf{H}}(f) \widehat{\mathbf{G}}^{\dagger}(f)+\widehat{\mathbf{H}}\left(f+\frac{1}{2}\right) \widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right)=0_{r}, \tag{3.5}
\end{equation*}
$$

and $\widehat{\Psi}(f)=\frac{1}{\sqrt{2}} \widehat{H}\left(\frac{f}{2}\right) \widehat{\phi}\left(\frac{f}{2}\right)$. If $\{\Psi(t-k): k \in \mathbb{Z}\}$ is an orthonormal basis for $\mathbf{W}_{0}$ then

$$
\langle\Psi, \Psi(t-k)\rangle=\int_{\mathbb{R}} \Psi(t) \Psi(t-k) d t=\mathbf{I}_{r} \delta_{k 0} \quad k \in \mathbb{Z},
$$

which implies the following relation for the matrix of wavelet mask function:

$$
\begin{equation*}
\sum_{k \in \mathbb{Z}} \mathbf{H}_{k} \mathbf{H}_{2 l+k}^{\dagger}=I_{r} \delta_{l 0}, \quad l \in \mathbb{Z} . \tag{3.6}
\end{equation*}
$$

This is equivalent to

$$
\begin{equation*}
\widehat{\mathbf{H}}(f) \widehat{\mathbf{H}}^{\dagger}(f)+\widehat{\mathbf{H}}\left(f+\frac{1}{2}\right) \widehat{\mathbf{H}}^{\dagger}\left(f+\frac{1}{2}\right)=2 I_{r} . \tag{3.7}
\end{equation*}
$$

Define $\widehat{\mathbf{M}}(f)=\left(\begin{array}{cc}\widehat{\mathbf{G}}(f) & \widehat{\mathbf{G}}\left(f+\frac{1}{2}\right) \\ \widehat{\mathbf{H}}(f) & \widehat{\mathbf{H}}\left(f+\frac{1}{2}\right)\end{array}\right)$ then equations (3.3),(3.5),(3.7) all together are equivalent to

$$
\begin{equation*}
\widehat{\mathbf{M}}(f) \widehat{\mathbf{M}}^{\dagger}(f)=2 I_{2 r}, \tag{3.8}
\end{equation*}
$$

which means $\widehat{\mathrm{M}}(f)$ is a paraunitary matrix.
3.2. Construction of filters. After constructing the mask function representation, now we are ready to describe and build filters. Suppose that $\widehat{\mathbf{G}}(f)$ is a finite polynomial matrix in $e^{-2 \pi i f}$, i.e. can be written in the form $\widehat{\mathbf{G}}(f)=$ $\sum_{l=0}^{L^{\prime}-1} \mathbf{G}_{l} e^{-2 \pi i f l}$ with $\widehat{\mathbf{G}}(0)=\sqrt{2} \mathbf{I}_{r}$, and satisfies (3.1). Then from [8] if

$$
\begin{equation*}
\inf _{|f| \leq \frac{1}{4}}\left|\lambda_{l}[\widehat{\mathbf{G}(f)}]\right|>0 \tag{3.9}
\end{equation*}
$$

for any eigenfunction $\lambda_{l}[\widehat{\mathbf{G}}(f)]$ of polynomial matrix $\widehat{\mathbf{G}}(f)$, the solution $\Phi(t)$ of the two-scale dilation equation is a matrix-valued scaling function for a matrixvalued MRA, and $\left\{\Psi_{j, k}(t)=2^{\frac{j}{2}} \Psi\left(2^{j} t-k\right): j, k \in \mathbb{Z}\right\}$ forms an orthonormal basis for matrix-valued space $L^{2}(\mathbb{R}, \mathbb{C}[r])$. For designing the matrix filters with transforms $\widehat{\mathbf{G}}(f)$ and $\widehat{\mathbf{H}}(f)$ that satisfies (3.2) and for that $\widehat{\mathbf{M}}(f)$ is paraunitary , we consider

$$
\begin{equation*}
\widehat{\mathbf{G}}(f)=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}\left(\mathbf{I}_{r}+e^{\epsilon 2 \pi i f} \widehat{\mathbf{P}}(2 f)\right), \quad \epsilon \in\{-1,1\} \tag{3.10}
\end{equation*}
$$

where $\gamma$ is a finite integer and $\widehat{\mathbf{P}}(2 f)$ is a (normalized ) paraunitary matrix, i.e. $\widehat{\mathbf{P}}(f) \widehat{\mathbf{P}}^{\dagger}(f)=\mathbf{I}_{r}$ which satisfies $\widehat{\mathbf{P}}(f+1)=\widehat{\mathbf{P}}(f)$, and such that $\widehat{\mathbf{P}}(0)=\mathbf{I}_{r}$. The matrix $\widehat{\mathbf{G}}(f)$ satisfies conditions (3.1) and (3.2). Notice that the eigenvalues of the polynomial matrix $\widehat{\mathbf{G}}(f)$ are related to the eigenvalues of $\widehat{\mathbf{P}}(2 f)$ via $\lambda_{l}[\widehat{\mathbf{G}}(f)]=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}\left\{1+e^{\epsilon 2 \pi i f} \lambda_{l}[\widehat{\mathbf{P}}(2 f)]\right\}$. Since $\widehat{\mathbf{M}}(f)$ is paraunitary, $\widehat{\mathbf{H}}(f)$ may be chosen as

$$
\begin{equation*}
\widehat{\mathbf{H}}(f)=e^{-2 \pi i f\left(L^{\prime}-1+\delta\right)} \widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right) \tag{3.11}
\end{equation*}
$$

where $L^{\prime}$ is the design length of the filter $\mathbf{G}_{l}$, and $\delta \in\{0,1\}$ is chosen so that $L^{\prime}-1+\delta$ is odd, because by 3.5

$$
\begin{gathered}
\widehat{\mathbf{H}}(f) \widehat{\mathbf{G}}^{\dagger}(f)+\widehat{\mathbf{H}}\left(f+\frac{1}{2}\right) \widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right) \\
=e^{-2 \pi i f\left(L^{\prime}-1+\delta\right)}\left[\widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right) \widehat{\mathbf{G}}^{\dagger}(f)+e^{-\pi i\left(L^{\prime}-1+\delta\right)} \widehat{\mathbf{G}}^{\dagger}(f) \widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right)\right] \\
=e^{-2 \pi i f\left(L^{\prime}-1+\delta\right)}\left[\widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right) \widehat{\mathbf{G}}^{\dagger}(f)-\widehat{\mathbf{G}}^{\dagger}(f) \widehat{\mathbf{G}}^{\dagger}\left(f+\frac{1}{2}\right)\right]=0_{r},
\end{gathered}
$$

which provide $\widehat{\mathbf{G}}(f)$ is commutative in the sense that $\widehat{\mathbf{G}}(f) \widehat{\mathbf{G}}\left(f+\frac{1}{2}\right)=\widehat{\mathbf{G}}(f+$ $\left.\frac{1}{2}\right) \widehat{\mathbf{G}}(f)$, and indeed this condition holds when $\widehat{\mathbf{G}}(f)$ is defined as in (3.10).
The matrix $\widehat{\mathbf{H}}$ given by (3.11) is a polynomial which can be written in the form

$$
\widehat{\mathbf{H}}=\sum_{m=\delta}^{L^{\prime}-1+\delta}(-1)^{L^{\prime}-1+\delta-m} \mathbf{G}_{L^{\prime}-1+\delta-m}^{\dagger} e^{-2 \pi i f m}
$$

If $L^{\prime}$ is even (and $\delta=0$ ), then comparison with $\widehat{\mathbf{H}}=\sum_{l=0}^{L^{\prime}-1} \mathbf{H}_{l} e^{-2 \pi i f l}$ we obtain $\mathbf{H}_{l}=(-1)^{l+1} \mathbf{G}_{L^{\prime}-l-1}^{\dagger}$ for $l=0,1, \ldots, L^{\prime}-1$ and we set $L=L^{\prime}$. If $L^{\prime}$ is odd $(\delta=1)$ we can increase the filter length to an even length $L^{\prime}+$ 1 by setting $\mathbf{G}_{L^{\prime}}=0_{r}$. Then we have $\mathbf{H}_{l}=(-1)^{l+1} \mathbf{G}_{\left(L^{\prime}+1\right)-l-1}^{\dagger}$ for $l=$
$0, \ldots, L^{\prime}$, with $\mathbf{H}_{0}=0_{r}$. In this case we set $L=L^{\prime}+1$. For constructing the matrix $\widehat{\mathbf{P}}(f)$ we first consider the class of paraunitary matrices, defined by $\widehat{\mathbf{P}}(f)=\widehat{\mathbf{U}}(f) \widehat{\mathbf{D}}(f) \mathbf{U}^{\dagger}(f)$, where $\widehat{\mathbf{U}}(f)$ is an arbitrary (normalized) paraunitary polynomial matrix with $\widehat{\mathbf{U}}(0)=\mathbf{I}_{r}$, and $\widehat{\mathbf{D}}(f)$ is a diagonal matrix with diagonal elements $\widehat{\mathbf{D}}_{l, l}=e^{-2 \pi i f k_{l}}, k_{l} \in\{0,1\}$. Using the general lattice structure, the $r \times r$-matrix $\widehat{\mathbf{U}}(f)$ may be constructed by $\widehat{\mathbf{U}}(f)=\widehat{\mathbf{U}}_{q}(f), \ldots, \widehat{\mathbf{U}}_{1}(f) \mathbf{F}$, where $q$ is a positive integer, $\mathbf{F}$ is an $r \times r$ constant unitary matrix, i.e. $\mathbf{F}^{\dagger} \mathbf{F}=\mathbf{F F}^{\dagger}$, and $\widehat{\mathbf{U}}_{l}(f)=I_{r}+\left(e^{2 \pi i f}-1\right) \mathbf{z}_{l} \mathbf{z}_{l}^{\dagger} l=0, \ldots, q$ with $\widehat{\mathbf{z}}_{l}^{\dagger} \mathbf{z}_{l}=1$, unit-norm constant $r \times 1$-vectors. The advantage of this construction is that the matrices $\widehat{\mathbf{D}}(f)$ and $\widehat{\mathbf{P}}(f)$ are similar and hence have the same eigenvalues, and those of $\widehat{\mathbf{D}}(f)$ are known. It is thus possible to compute the eigenvalues of $\widehat{\mathbf{G}}(f)$ to check that the sufficient condition (3.9) is satisfied.

## 4. Main Results for $\left.\mathbb{C l}\left(\mathbb{R}^{4}\right)\right)$-MRA

Case I:
Let $r=4$, by the previous section $\widehat{\mathbf{D}}_{l, l}=e^{-2 \pi i k f}, k \in\{0,1\}, l=1,2,3,4$. So we have

$$
\widehat{\mathbf{P}}(f)=\widehat{\mathbf{U}}(f) \widehat{\mathbf{D}}(f) \mathbf{U}^{\dagger}(f)
$$

If $\widehat{\mathbf{U}}(f)=\mathbf{I}_{4}, \widehat{\mathbf{U}}$ is a paraunitary polynomial matrix which $\widehat{\mathbf{U}}(0)=\mathbf{I}_{4}$, so $\widehat{\mathbf{P}}(f)=e^{-2 \pi i k f} \mathbf{I}_{4}$, this gives the diagonal matrix $\widehat{\mathbf{G}}(f)=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}\left(1+e^{(\epsilon-2 k) 2 \pi i f}\right) \mathbf{I}_{4}$. $\widehat{\mathbf{G}}(f)$ has only one eigenvalue which is repeated and is $\lambda[\widehat{\mathbf{G}}(f)]=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}(1+$ $\left.e^{(\epsilon-2 k) 2 \pi i f}\right)$. Now if we set $\epsilon=1$ we obtain

$$
\begin{aligned}
& \lambda[\widehat{\mathbf{G}}(f)]=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}\left(1+e^{2 \pi i f}\right),(k=0) \\
& \lambda[\widehat{\mathbf{G}}(f)]=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}\left(1+e^{-2 \pi i f}\right),(k=1)
\end{aligned}
$$

which in both case the condition $|\lambda[\widehat{\mathbf{G}}(f)]|=\sqrt{1+\cos 2 \pi f}>0 \quad$, for $|f| \leq \frac{1}{4}$, is fullfaith. Hence the sufficient condition (3.9) is satisfied.
If we set $\gamma=0, \epsilon=1, k=1$, then

$$
\widehat{\mathbf{G}}(f)=\frac{1}{\sqrt{2}}\left(\begin{array}{cccc}
1+e^{-2 \pi i f} & 0 & 0 & 0 \\
0 & 1+e^{-2 \pi i f} & 0 & 0 \\
0 & 0 & 1+e^{-2 \pi i f} & 0 \\
0 & 0 & 0 & 1+e^{-2 \pi i f}
\end{array}\right)
$$

Let $f=0$, then $\widehat{\mathbf{G}}(0)=\sqrt{2} \mathbf{I}_{4}, \widehat{\mathbf{G}}\left(\frac{1}{2}\right)=0_{4}$ and in comparison with $\widehat{\mathbf{G}}(f)=$ $\sum_{l=0}^{L^{\prime}-1} \mathbf{G}_{l} e^{-2 \pi i f l}$ we have

$$
\widehat{\mathbf{G}}(f)=\left(\begin{array}{cccc}
\frac{1}{\sqrt{2}} & 0 & 0 & 0 \\
0 & \frac{1}{\sqrt{2}} & 0 & 0 \\
0 & 0 & \frac{1}{\sqrt{2}} & 0 \\
0 & 0 & 0 & \frac{1}{\sqrt{2}}
\end{array}\right)+\left(\begin{array}{cccc}
\frac{1}{\sqrt{2}} & 0 & 0 & 0 \\
0 & \frac{1}{\sqrt{2}} & 0 & 0 \\
0 & 0 & \frac{1}{\sqrt{2}} & 0 \\
0 & 0 & 0 & \frac{1}{\sqrt{2}}
\end{array}\right) e^{-2 \pi i f}
$$

This means that $\mathbf{G}_{0}=\mathbf{G}_{1}=\frac{1}{\sqrt{2}} \mathbf{I}_{4}$ so, $\mathbf{H}_{l}=(-1)^{l+1} \mathbf{G}_{L-l-1}^{\dagger}$ for $l=0,1$.
Case II:
From now on we consider $\widehat{\mathbf{G}}(f)=\frac{e^{2 \pi i f \gamma}}{\sqrt{2}}\left(\mathbf{I}_{4}+e^{\epsilon 2 \pi i f} \widehat{\mathbf{P}}(2 f)\right)$, we can make $\widehat{\mathbf{P}}(f)$ as

$$
\widehat{\mathbf{P}}(f)=\widehat{\mathbf{U}}(f) \widehat{\mathbf{D}}(f) \mathbf{U}^{\dagger}(f)
$$

(for $L_{\mathbf{M}_{Q}}^{2}(\mathbb{R}, \mathbb{C}[4])$ we set $\left.\widehat{\mathbf{U}}(f) \in \mathbf{M}_{Q} \bigcap \mathbf{U}(4)\right)$.
Set $q=1$ and $\mathbf{F}=4 \times 4$-rotation matrix

$$
\mathbf{F}=\left[\begin{array}{cccc}
\cos \theta & -\sin \theta & 0 & 0 \\
\sin \theta & \cos \theta & 0 & 0 \\
0 & 0 & \cos \theta & -\sin \theta \\
0 & 0 & \sin \theta & \cos \theta
\end{array}\right]
$$

(note that $\left.\mathbf{F} \in \mathbf{M}_{Q}\right)$. Then $\widehat{\mathbf{U}}(f)=\widehat{\mathbf{U}_{1}}(f) \mathbf{F}$ such that $\widehat{\mathbf{U}_{1}}(f)=\mathbf{I}_{4}+\left(e^{2 \pi i f}-\right.$ 1) $\mathbf{z}_{1} \mathbf{z}_{1}^{\dagger}$.

Now let $\mathbf{z}_{1}=\frac{e^{i \theta}}{\alpha}(a, b, c, d)^{T}$ so $\mathbf{z}_{1}^{\dagger}=\frac{e^{-i \theta}}{\alpha}(a, b, c, d)$ such that $\alpha=a^{2}+b^{2}+c^{2}+d^{2}$. For instant if $(a, b, c, d)=(0,0,0, \alpha), \alpha \in \mathbb{R}$, then $\mathbf{z}_{1} \mathbf{z}_{1}^{\dagger}$ is a $4 \times 4$-matrix with all entiers zero except $e_{4,4}=1$, so $\mathbf{U}_{1}(f)$ is the same matrix with $e_{4,4}=e^{2 \pi i f}$ and by choosing $\mathbf{D}$ such that $\mathbf{D}_{1,1}=1, \mathbf{D}_{2,2}=\mathbf{D}_{3,3}=\mathbf{D}_{4,4}=e^{-2 \pi i f}$ finally we have:
(4.1)
$\widehat{\mathbf{G}}(f)=\frac{1}{\sqrt{2}}\left(\begin{array}{cccc}\cos ^{2} \theta+e^{-2 \pi i f}+e^{-4 \pi i f} \sin ^{2} \theta & \sin \theta \cos \theta-e^{-4 \pi i f} \sin \theta \cos \theta & 0 & 0 \\ \sin \theta \cos \theta-e^{-4 \pi i f} \sin \theta \cos \theta & e^{-2 \pi i f}+\sin ^{2} \theta+e^{-4 \pi i f} \cos 2 \theta & 0 & 0 \\ 0 & 0 & 2 e^{-2 \pi i f} & 0 \\ 0 & 0 & 0 & 2 e^{-2 \pi i f}\end{array}\right)$
This means that $\mathbf{G}_{0}=\frac{1}{\sqrt{2}}\left(\begin{array}{cccc}\cos ^{2} \theta & \sin \theta \cos \theta & 0 & 0 \\ \sin \theta \cos \theta & \sin ^{2} \theta & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0\end{array}\right), \mathbf{G}_{1}=\frac{1}{\sqrt{2}}\left(\begin{array}{llll}1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 2\end{array}\right)$
$\mathbf{G}_{2}=\frac{1}{\sqrt{2}}\left(\begin{array}{cccc}\sin ^{2} \theta & \sin \theta \cos \theta & 0 & 0 \\ \sin \theta \cos \theta & \cos ^{2} \theta & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0\end{array}\right)$, and since $L^{\prime}-1=3$ then $L^{\prime}=4$ so $\delta=0$.
Then we set $L=L^{\prime}=4$.
Now by $\mathbf{H}_{l}=(-1)^{l+1} \mathbf{G}_{L^{\prime}-l-1}^{\dagger}, \quad(l=0,1,2,3)$ we have

$$
\mathbf{H}_{0}=-\mathbf{G}_{3}^{\dagger}=0_{4}, \mathbf{H}_{1}=\mathbf{G}_{2}^{\dagger}, \mathbf{H}_{2}=-\mathbf{G}_{1}^{\dagger}, \mathbf{H}_{3}=\mathbf{G}_{0}^{\dagger}
$$

So from (3.1) and (3.2) we obtain the desired wavelets.
